

Introduction

Diagnosis of early preg. is based primarily upon laboratory assessment of human chorionic gonadotrophin (hCG) in urine or blood

Ultrasound is also an accurate method of diagnosis

INTRODUCTION

- ↳ Presumptive signs
- ↳ Probable signs
- ↳ Positive signs

Dating a pregnancy

- Also known as **Gestational age**
- From the day of the last menstrual period (LMP)
- 9 months & 7 days
- 280 days
- 40 weeks

Expected date of delivery (EDD)

- Calculated by the date of LMP, counting forwards 9 months & adding 7 days in a 28 day cycle
- If the cycle is longer than 28 days, add the difference b/w the cycle length & 28 to compensate
- Gestational calendar wheels

Symptoms of pregnancy

Cessation of menstruation

Subjective symptoms

Morning sickness

Irritation of breasts

Nausea & vomiting

Fatigue

Increase in frequency of micturition

Signs of pregnancy

BREASTS: Fullness

Areola pigmentation

Montgomery's
tuberles,
hypertrophied
sebaceous glands

FACE: Brown
pigmentation, mask
- usually patchy
(cholasma)

Diagnosis in the first trimester (first 12 weeks)

Symptoms:

- ❖ 1. Cessation of menstruation (missed period)
 - Due to increase in estrogen & progesterone production by corpus luteum
 - HARTMAN'S SIGN/ PLACENTAL SIGN
 - Slight bleeding at the expected time of menstruation, occurs rarely in first 3 mnths. Scanty
 - Shouldn't get confused → with threatened abortion

❖ 2. Morning sickness: 50% of cases

- Usually follows soon after the missed period
- Nausea/vomiting esp. in the morning on rising from bed
- Usually disappears after the 3rd month

❖ 3. Frequency of micturition:

- Due to congestion of the bladder mucosa, irritation of bladder by preg. Uterus
- Resting of the bulky uterus on the UB, anteverted position
- Change in maternal osmoregulation- increase in thirst & polyuria
- Usually disappears after the 3rd month

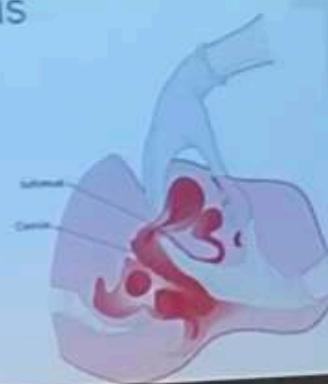

- ❖ 4. **Breast symptoms:** Enlargement, heaviness, discomfort, pricking sensation--> 6th to 8th week
- ❖ 5. **Apetite change:** craving for certain foods & refusal for some
- ❖ 6. **Fatigue:** Sleepiness

Objective signs

1. **Breast signs:** Evident in Primigravida - 6-8 weeks
 - Increase in size & vascularity- dilated visible veins
 - Increase pigmentation of nipple & areola, secondary areola
 - Montgomery tubercles appear in areola- dilated sebaceous glands
 - Expression of colostrum- (thick yellow secretion) as early as 12 weeks

2. Uterine sign: Felt by bimanual examination:

- Size: Enlarged
- Consistency: soft
- Shape: globular
- Uterus remains a pelvic organ upto 12 weeks, felt just per abdomen as a suprapubic bulge
- Hegar's sign of pregnancy:
 - Bimanual palpation of soft uterine isthmus b/w the cervix & the body
 - Cystic sensation of uterus by 8 weeks

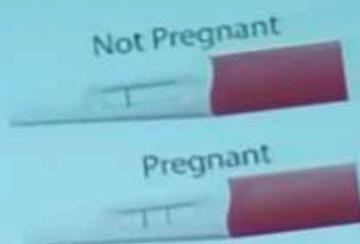

Pelvic changes

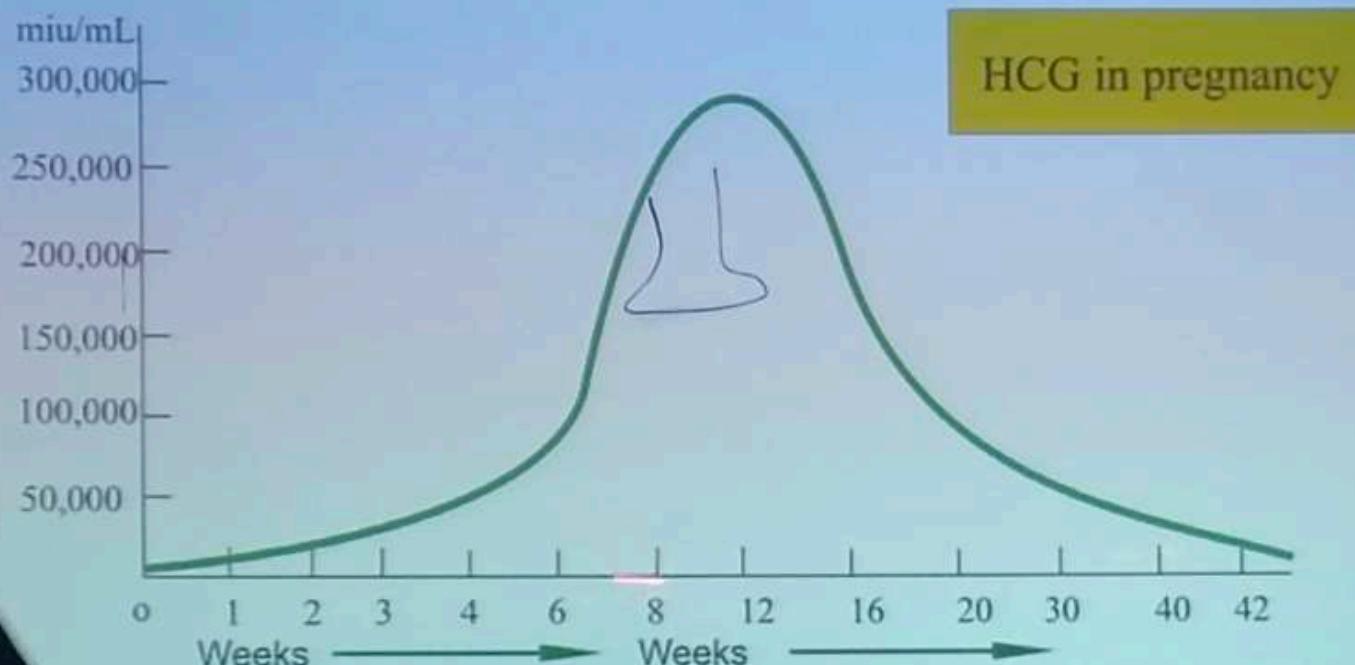

- **Jacquemier's sign:**
- Dark bluish discolouration of mucous membrane of vagina
- **Leukorrhea:** Increase in vaginal discharge

Immunologic al tests

1. HCG:

- This hormone is released by the trophoblastic tissue produced by the growing fetus & placenta
- Detection of HCG in the maternal serum or urine evident only 3-10 days after conception
- Detectable in the serum of approx. 5% of pts. 8 days after conception & more than 98% of pts. by day 11
- Levels peak at 10-12 weeks gestation & then plateau before falling

Ultrasound

2. ULTRASOUND:

- Intradecidual gestational sac is identified as early as 29-35 days of gestation
- Gestational sac & yolk sac – 5 menstrual weeks
- Fetal pole & cardiac activity – 6 weeks
- Embryonic movements – 7 weeks
- Number of fetuses
- To establish dates
- Doppler effect of USG can pick heart rate reliably by 10 th week

Diagnosis in the second trimester (13-28 weeks)

Symptoms:

- 1. Amenorrhea
- 2. Morning sickness & urinary symptoms gradually decrease
- 3. Quicken^g: perception of fetal movements by the preg. Woman
 - a. 18-20 weeks—In primigravida
 - b. 16-18 weeks — In multipara
- 4. Abdominal enlargement

Inspection:

LINEA NIGRA:

- Extending from the pubic symphysis to ensiform cartilage
- 20 th week

STRIAE:

- (Both pink & white) visible in the lower abdomen more towards the flanks

Abdomen

ABDOMEN:

Linea nigra: brown or black pigmentation, stretching of collagen & elastin

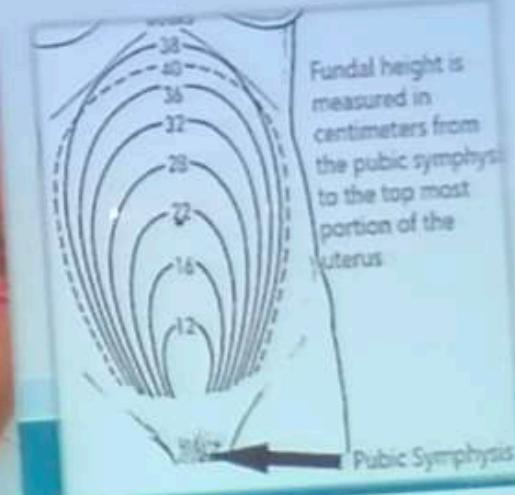

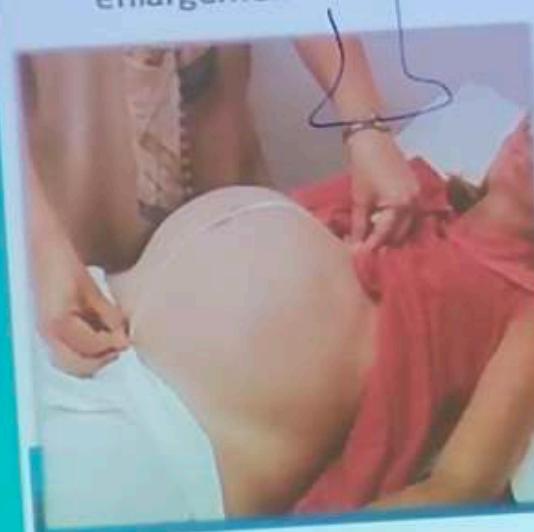

Striae gravidarum: stretch marks, red or purple during preg. Turns on to white after preg.

Situated in the lower abdomen, breasts, thighs & buttocks

Palpation: uterus is palpable at 12 weeks of gestation

Palpation

- PALPATION:
 - Fundal height – increased with progressive enlargement of the uterus.

Palpation

- Uterus is abdominally felt (ovoid) feels soft & elastic
- **BRAXTON HICKS CONTRACTIONS:** Intermittent painless contractions detected by abdominal examination
- Active fetal movements can be felt at intervals by placing the hand on the uterus as early as 20 weeks

Abdominal exam.

- External ballottement: Elicited at 20th week by abdominal examination
- Palpation of the fetal parts & palpation of fetal movements by obstetrician by 20 weeks

Auscultation

- Auscultation of fetal heart sounds as early as 20-24 weeks by Pinnard stethoscope

tourniquet to auscultate
heart sounds

Investigations

SONOGRAPHY: At 18-20 weeks permits a detailed survey of fetal anatomy, placental localisation & integrity of cervical canal

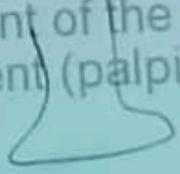

- FETAL ORGAN ANATOMY: to detect any malformation
- FETAL VIABILITY:

anomaly scan

Diagnosis in the 3 rd trimester (29- 40 weeks)

Symptoms:

- Amenorrhea persists
- Enlargement of the abdomen- leading to discomfort to the patient (palpitation or dyspnea following exertion)

- LIGHTENING: 38 weeks
- Sense of relief of pressure symptoms d/t engagement of the presenting part
- Frequency of micturition reappears
micturition as head descended in pelvis
- Fetal movements are more pronounced

dyspnea as diaphragm moved upwards

Signs:

- Cutaneous changes are more prominent with increase pigmentation & striae
- **UTERINE SHAPE:** from cylindrical to spherical beyond 36 weeks
- **FUNDAL HEIGHT:** at the level of ensiform cartilage at 36 weeks
- Comes to 32 week level at 40 th week because of engagement of the fetal part

Syphphysio- fundal height

SFH: Upper border of the fundus located by the ulnar border of the left hand & point is marked

- Distance b/w the upper border of symphysis pubis upto the point marked is measured in cms.
- After 24 weeks the SFH in cm. corresponds to the number of weeks upto 36 weeks
- Braxton hicks contractions: more evident
- Fetal movements: easily felt

- Palpation of the fetal parts & their identification becomes much easier as baby size is larger now

- F.H.S— heard distinctly

- **SONOGRAPHY:**

- Fetal growth assessment— Can be made more accurate

- Amniotic fluid volume assessment—For oligohydramnios /polyhydramnios

abdominal circumference is measured
for fetal weight assessment

oligohydramnios is dec amount of
amniotic fluid and polyhydramnios is
inc amniotic fluid esp in GDM

Differential diagnosis

- Uterine fibroid
- Cystic ovarian tumour – (Amenorrhea is absent, firm, hard positive sign absent, USG)
- Distended urinary bladder—catheterization solves the problem
- Haematometra
- Pseudocyesis

Important definitions

- Gravid
 - Parous
 - Primigravida
 - Multigravida
 - Grand multiparous
- primigravida is first baby
nulliparous is no baby present
- nulliparous or nullipara
multiparous
multigravida is numerous babies
- more than 5 children is grand multiparous

TABLE 134-4 INFECTIOUS AGENTS ASSOCIATED WITH THE DEVELOPMENT OF LYMPHOID MALIGNANCIES

Infectious Agent	Lymphoid Malignancy
Epstein-Barr virus	Burkitt's lymphoma Post-organ transplant lymphoma Primary CNS diffuse large B-cell lymphoma <u>Hodgkin's lymphoma</u>
HTLV-1	Extranodal NK/T-cell lymphoma, nasal type
HIV	Adult T-cell leukemia/lymphoma Diffuse large B-cell lymphoma Burkitt's lymphoma
Hepatitis C virus	Lymphoplasmacytic lymphoma
<i>Helicobacter pylori</i>	Gastric MALT lymphoma
Human herpesvirus 8	Primary effusion lymphoma Multicentric Castleman's disease

Abbreviations: CNS, central nervous system; HIV, human immunodeficiency virus; HTLV, human T-cell lymphotropic virus; MALT, mucosa-associated lymphoid tissue; NK, natural killer.
